Field of the Invention The present invention relates to a semiconductor memory device, and more particularly, to a semiconductor memory device in which a redundancy circuit for repairing defects in memory cells in a memory cell array is provided. 2. Description of the Prior Art In a semiconductor memory device, a plurality of memory cells are arranged in rows and columns so that the entire memory cell array can be identified by the unique combination of row and column addresses. A redundancy circuit is generally provided for replacing defective memory cells detected during testing with non-defective memory cells. Memory cell addresses in the vicinity of defective memory cells are designated as spare rows or spare columns which replace defective rows or defective columns. The redundancy circuit replaces a defective row or column with one of the spare rows or spare columns. In an RAM (Random Access Memory), addresses are assigned to respective memory cells by rows and columns. When defective memory cells are detected during testing, defective columns or rows are replaced with spare columns or rows, respectively. In a ROM (Read Only Memory), address designation information is assigned to memory cells, and defective memory cells are replaced with non-defective memory cells which are all of the same type. The present invention will be described with respect to a DRAM (Dynamic Random Access Memory) whose memory cells are arranged in a matrix of rows and columns. FIG. 1 shows a plan view of a memory cell array which is divided into four blocks, (block 0 to block 3). The memory cell array is divided into four blocks, wherein each of the blocks is divided into four groups of memory cells (block 0), (block 1), (block 2), and (block 3). Block 0 includes memory cells (M0 to M7) arranged in 8 rows and 32 columns, respectively. Block 1 includes memory cells (M8 to M15) arranged in 8 rows and 32 columns, respectively. Block 595f342e71
